Branch Turnaround Power BI Dashboard

Requirements & Analysis Document

Oct 26, 2026 · Prepared by @PRATIK MISHRA

1. Introduction

This document captures the business analysis behind a self-directed Power BI analytics exercise modeling branch counter operations. It analyzes 2 years of simulated branch service data across 4 branches to understand customer wait-time drivers, using 12 DAX measures in an interactive dashboard to surface the operational bottlenecks and support a digital-channel migration recommendation — the format a Business Analyst would present to a cluster or branch operations head.

The underlying dataset is simulated to realistic industry parameters, not drawn from a live branch network.

2. Business Problem

Branch counters handle every transaction type identically, with no visibility into which transaction types actually consume the most counter time. This makes it impossible for branch and cluster management to target operational improvements — wait-time complaints are addressed branch-by-branch and anecdotally, rather than by identifying and fixing the specific transaction types driving the bulk of customer wait time across the network.

3. Project Objective

- Model 2 years of branch service data across 4 branches to analyze transaction-level wait-time performance.
- Build an interactive Power BI dashboard with DAX measures to monitor service KPIs by branch and transaction type.
- Identify the transaction types responsible for the majority of counter wait time.
- Translate the findings into a business recommendation on which transaction types to shift to digital channels.

4. Scope

In scope: branch counter transaction and wait-time data across 4 branches over a 2-year window; transaction-type-level KPI analysis; dashboard build; digital-channel migration recommendation.

Out of scope: staffing-level optimization, branch layout/physical redesign, and any change to the digital-channel platform itself beyond routing recommendations.

5. Stakeholders

Role	Stakeholder	Interest / Influence
Business Sponsor	Cluster Head	Owns branch service-level targets across the 4 branches
Process Owner	Branch Operations Manager	Accountable for counter-level service delivery
Analyst	Pratik Kumar (Business/Data Analyst)	Builds the dashboard and the recommendation
Digital Channel Team	Digital Banking Team	Receives and absorbs the migrated transaction volume
Customer	Branch Walk-in Customer	Experiences wait time directly

6. Existing AS-IS Process (branch counter operations)

All transaction types — from simple balance inquiries and cash deposits to more complex requests — are handled at the same physical counters with the same staffing model, regardless of how much counter time each type actually consumes. There is no routine measurement of wait time by transaction type, only branch-level, anecdotal feedback. No data-driven case exists for which transaction types should be pushed toward digital channels.

7. Problems in Current Process

- No transaction-type-level visibility into what drives counter wait time.

- Service improvement efforts are reactive and branch-specific rather than network-wide and data-driven.
- High-volume, low-complexity transaction types occupy counter time that could be shifted to digital channels.
- No standing KPI dashboard for cluster-level comparison across branches.
- Customer wait-time complaints are the primary (lagging) signal, rather than a leading operational metric.

8. Proposed TO-BE Process (digital-channel shift)

The dashboard analysis identified that 2 transaction types account for 54% of total counter wait time across the 4 branches. Both are transaction types with existing digital-channel equivalents. The proposed TO-BE state routes these transaction types to the digital channel by default, with counter service retained only as a fallback, freeing counter capacity for transaction types that genuinely require in-person handling.

9. Business Requirements

ID	Requirement
BR-01	Measure counter wait time at the transaction-type level, not just branch level
BR-02	Rank transaction types by their share of total counter wait time
BR-03	Provide a single dashboard comparable across all 4 branches
BR-04	Identify transaction types suitable for default digital-channel routing
BR-05	Present findings as an actionable recommendation for cluster leadership

10. Functional Requirements

ID	Functional Requirement	Linked BR
FR-01	Dashboard shall display average and total wait time by transaction type, filterable by branch	BR-01
FR-02	Dashboard shall rank transaction types by their percentage share of total counter wait time	BR-02
FR-03	Dashboard shall support branch-to-branch comparison across all 4 branches on one page	BR-03
FR-04	Dashboard shall flag transaction types that both have a digital-channel equivalent and are high wait-time contributors	BR-04
FR-05	Dashboard shall support a 2-year trend view to show seasonality in wait time	BR-01
FR-06	A one-page summary view shall be exportable for non-technical stakeholders	BR-05

11. Non-Functional Requirements

Category	Requirement
Performance	Dashboard refresh completes in under 30 seconds over the full 2-year, 4-branch dataset
Usability	Readable at a glance by a cluster head with no Power BI/DAX background
Data Privacy	No customer-identifying fields included; transaction-type and timestamp data only
Accuracy	DAX measures validated against a manual sample calculation before publishing
Maintainability	Dashboard refreshes on new data without requiring measure rebuilds

12. User Stories

ID	User Story
US-01	As a cluster head, I want wait time broken down by transaction type, so that I know what's actually driving counter delays.
US-02	As a branch operations manager, I want to compare my branch's KPIs against the other 3 branches, so that I can benchmark performance.
US-03	As a cluster head, I want transaction types with a digital equivalent flagged if they drive high wait time, so that I have a clear migration candidate list.
US-04	As a cluster head, I want a one-page exportable summary, so that I can present the recommendation without walking through the full dashboard.
US-05	As a branch operations manager, I want a 2-year trend view, so that I can see whether wait-time issues are seasonal or structural.

13. Acceptance Criteria

US-01 — Wait time by transaction type

- Given 2 years of branch service data, when the dashboard aggregates wait time by transaction type, then each type's average and total wait time is shown, ranked by contribution.
- Given the ranked list, when the top types are summed, then the dashboard shows the minimum set of types accounting for ≥50% of total wait time.

US-03 — Digital-migration candidates

- Given a transaction type has a digital-channel equivalent, when it also ranks among the top wait-time contributors, then it is flagged as a migration candidate on the dashboard.

US-05 — Trend view

- Given the 2-year dataset, when the trend view is filtered to a date range, then wait time by month is displayed for the selected branch(es).

14. Business Rules

ID	Rule
BRule-01	A transaction type is a digital-migration candidate only if it has an existing, functioning digital-channel equivalent.
BRule-02	Counter service remains available as a fallback for any migrated transaction type — no transaction type is removed from counters entirely.
BRule-03	Wait time is measured from customer queue entry to transaction completion, consistently across all 4 branches.
BRule-04	Dashboard KPIs are refreshed on the same cadence across all branches to keep comparisons valid.

15. Process Flow / Dashboard Methodology

1. Modeled 2 years of branch service data across 4 branches in Power BI, with transaction type, branch, and timestamp as core dimensions.
2. Built 12 DAX measures covering average/total wait time, transaction volume, and share-of-total calculations by type and branch.
3. Ranked transaction types by wait-time contribution and identified that 2 types account for 54% of total counter wait time.
4. Cross-referenced those types against existing digital-channel capability to shortlist migration candidates.
5. Packaged the dashboard with a one-page summary and presented the recommendation to shift the flagged transaction types toward digital-channel processing.

16. Assumptions

- The simulated 2-year, 4-branch dataset reflects realistic transaction-mix and wait-time patterns for a retail branch network.
- The flagged transaction types' digital-channel equivalents can absorb additional volume without a separate capacity upgrade.
- Wait-time measurement methodology is consistent across all 4 branches over the full 2-year window.
- The 54% figure is based on the analyzed dataset and would need revalidation against live data before being used as an audited operational KPI.

17. Risks

Risk	Likelihood	Impact	Mitigation
Digital channel cannot absorb migrated volume without degrading its own service	Medium	High	Phase the migration and monitor digital-channel load before full rollout
Customers resist self-service for migrated transaction types	Medium	Medium	Keep counter fallback available (BRule-02) and provide in-branch digital assistance initially
Simulated data distribution diverges from a specific live branch's mix	Low	Medium	Validate findings against a live sample from each branch before acting network-wide
Stakeholders treat the 54% figure as an audited KPI rather than an analysis estimate	Medium	Low	Clearly label it as dataset-derived in all reporting

18. Success Metrics

Metric	Baseline	Target
Branches covered	1 at a time (anecdotal)	4, on one comparable dashboard

Metric	Baseline	Target
Data window	Ad hoc	2 years, continuously refreshed
DAX measures built	—	12
Wait-time visibility	Branch-level only	Transaction-type level across all branches
Top wait-time contributors identified	Unranked	2 transaction types = 54% of wait time
Migration candidates flagged	0	2, with a routing recommendation
